Outline

- Scatterplots
- Pearson's r and r^2
 - Explain the concepts of total, explained, and unexplained variance
 - Test Pearson's r for significance: five-step model

Scatterplots

- Scatterplots have two dimensions
 - The independent variable (X) is displayed along the horizontal axis
 - The dependent variable (Y) is displayed along the vertical axis
- Each dot on a scatterplot is a case
 - The dot is placed at the intersection of the case's scores on X and Y
- Inspection of a scatterplot should always be the first step in assessing the association between two interval-ratio level variables

Example of a scatterplot

- Number of children (X) and hours per week husband spends on housework (Y) at dual-career households

Regression line

- A regression line is added to the graph
- It summarizes the linear correlation between X and Y
 - This straight line connects all of the dots
 - Or this line comes as close as possible to connecting all of the dots

Scatterplot with regression line

Husband's Housework by Number of Children

Use of scatterplots

- Scatterplots can be used to answer these questions
 1. Is there an association?
 2. How strong is the association?
 3. What is the pattern of the association?

1. Is there an association?

- An association exists if the conditional means of Y change across values of X
- If the regression line has an angle to the X axis
 - We can conclude that an association exists between the two variables
 - The line is not parallel to the X axis

2. How strong is the association?

- Strength of the correlation is determined by the spread of the dots around the regression line
- In a perfect association
 - All dots fall on the regression line
- In a stronger association
 - The dots fall close to the regression line
- In a weaker association
 - The dots are spread out relatively far from the regression line

3. Pattern of the association

- The pattern or direction of association is determined by the angle of the regression line

Positive (a), Negative (b), and Zero (c) Relationships

Check for linearity

- Scatterplots can be used to check for linearity
 - An assumption of scatterplots and linear regression analysis is that X and Y have a linear correlation
 - In a linear association, the dots of a scatterplot form a straight line pattern

Husband's Housework by Number of Children

Nonlinear associations

- In a nonlinear association, the dots do not form a straight line pattern

Some Nonlinear Relationships

GSS: Income by education

Figure 1. Respondent's income by years of schooling, U.S. adult population, 2016

$$\text{Income} = -26,219.18 + 4,326.10(\text{Years of schooling})$$

Note: The scatterplot was generated without the complex survey design of the General Social Survey. The regression was generated taking into account the complex survey design of the General Social Survey.

TEXAS A&M
UNIVERSITY.

Pearson's r

- Pearson's r is a measure of association for interval-ratio level variables

$$r = \frac{\sum(X - \bar{X})(Y - \bar{Y})}{\sqrt{[\sum(X - \bar{X})^2][\sum(Y - \bar{Y})^2]}}$$

- Pearson's r indicate the direction of association
 - -1.00 indicates perfect negative association
 - 0.00 indicates no association
 - $+1.00$ indicates perfect positive association
- It doesn't have a direct interpretation of strength

Coefficient of determination (r^2)

- For a more direct interpretation of the strength of the linear association between two variables
 - Calculate the coefficient of determination (r^2)
- The coefficient of determination informs the percentage of the variation in Y explained by X
- It uses a logic similar to the proportional reduction in error (PRE) measure
 - Y is predicted while ignoring the information on X
 - Mean of the Y scores: \bar{Y}
 - Y is predicted taking into account information on X

Predicting Y without X

- The scores of any variable vary less around the mean than around any other point
 - The vertical lines from the actual scores to the predicted scores represent the amount of error of predicting Y while ignoring X

Predicting Y Without X (dual-career families)

Predicting Y with X

- If the Y and X have a linear association
 - Predicting scores on Y from the least-squares regression equation will incorporate knowledge of X
 - The vertical lines from each data point to the regression line represent the amount of error in predicting Y that remains even after X has been taken into account

$$Y' = a + bX$$

Predicting Y with X (dual-career families)

Estimating r^2

- **Total variation**: $\sum(Y - \bar{Y})^2$
 - Gives the error we incur by predicting ***Y without knowledge of X***
- **Explained variation**: $\sum(Y' - \bar{Y})^2 = \sum(\hat{Y} - \bar{Y})^2$
 - Improvement in our ability to predict ***Y when taking X into account***
- r^2 indicates how much X helps us predict Y

$$r^2 = \frac{\sum(\hat{Y} - \bar{Y})^2}{\sum(Y - \bar{Y})^2} = \frac{\text{Explained variation}}{\text{Total variation}}$$

Unexplained variation

- **Unexplained variation**: $\sum(Y - Y')^2 = \sum(Y - \hat{Y})^2$
 - Difference between our best prediction of Y with X (Y') and the actual scores (Y)
 - It is the aggregation of vertical lines from the actual scores to the regression line
 - This is the amount of error in predicting Y that remains after X has been taken into account
 - It is caused by omitted variables, measurement error, and/or random chance
 - This is the residual of the regression

Example: Pearson's r

- Number of children (X) and hours per week husband spends on housework (Y)

Computation of Pearson's r

1	2	3	4	5	6	7
X	$X - \bar{X}$	Y	$Y - \bar{Y}$	$(X - \bar{X})(Y - \bar{Y})$	$(X - \bar{X})^2$	$(Y - \bar{Y})^2$
1	-1.67	1	-2.33	3.89	2.79	5.43
1	-1.67	2	-1.33	2.22	2.79	1.77
1	-1.67	3	-0.33	0.55	2.79	0.11
1	-1.67	5	1.67	-2.79	2.79	2.79
2	-0.67	3	-0.33	0.22	0.45	0.11
2	-0.67	1	-2.33	1.56	0.45	5.43
3	0.33	5	1.67	0.55	0.11	2.79
3	0.33	0	-3.33	-1.10	0.11	11.09
4	1.33	6	2.67	3.55	1.77	7.13
4	1.33	3	-0.33	-0.44	1.77	0.11
5	2.33	7	3.67	8.55	5.43	13.47
<u>5</u>	<u>2.33</u>	<u>4</u>	<u>0.67</u>	<u>1.56</u>	<u>5.43</u>	<u>0.45</u>
32	-0.04	40	0.04	18.32	26.68	50.68

Example: calculate r

$$r = \frac{\sum(X - \bar{X})(Y - \bar{Y})}{\sqrt{[\sum(X - \bar{X})^2][\sum(Y - \bar{Y})^2]}}$$

$$r = \frac{18.32}{\sqrt{(26.68)(50.68)}}$$

$$r = 0.50$$

Example: interpretation

- $r = 0.50$
 - The association between X and Y is positive
 - As the number of children increases, husbands' hours of housework per week also increases
- $r^2 = (0.50)^2 = 0.25$
 - The number of children explains 25% of the total variation in husbands' hours of housework per week
 - We make 25% fewer errors by basing the prediction of husbands' housework hours on number of children
 - We make 25% fewer errors by using the regression line
 - As opposed to ignoring the X variable and predicting the mean of Y for every case

Test Pearson's r for significance

- Use the five-step model
 1. Make assumptions and meet test requirements
 2. Define the null hypothesis (H_0)
 3. Select the sampling distribution and establish the critical region
 4. Compute the test statistic
 5. Make a decision and interpret the test results

Step 1: Assumptions, requirements

- Random sampling
- Interval-ratio level measurement
- Bivariate normal distributions
- Linear association
- Homoscedasticity
 - The variance of Y scores is uniform for all values of X
 - If the Y scores are evenly spread above and below the regression line for the entire length of the line, the association is homoscedastic
- Normal sampling distribution

Figure 2.10 "All clear" e -versus- \hat{Y} plot (artificial data).

Influential Case

Curvilinear Relation

Nonnormal Residual Distribution

Heteroscedasticity

Figure 2.11 Examples of trouble seen in e -versus- \hat{Y} plots (artificial data).

Step 2: Null hypothesis

- Null hypothesis, $H_0: \rho = 0$
 - H_0 states that there is no correlation between the number of children (X) and hours per week husband spends on housework (Y)

- Alternative hypothesis, $H_1: \rho \neq 0$
 - H_1 states that there is a correlation between the number of children (X) and hours per week husband spends on housework (Y)

Step 3: Distribution, critical region

- Sampling distribution: Student's t
- Alpha = 0.05 (two-tailed)
- Degrees of freedom = $n - 2 = 12 - 2 = 10$
- $t(\text{critical}) = \pm 2.228$

Step 4: Test statistic

$$t(\textit{obtained}) = r \sqrt{\frac{n - 2}{1 - r^2}}$$

$$t(\textit{obtained}) = (0.50) \sqrt{\frac{12 - 2}{1 - (0.50)^2}}$$

$$t(\textit{obtained}) = 1.83$$

Step 5: Decision, interpret

- $t(\text{obtained}) = 1.83$
 - This is not beyond the $t(\text{critical}) = \pm 2.228$
 - The $t(\text{obtained})$ does not fall in the critical region, so we **do not reject** the H_0
- The two variables are not correlated in the population
 - The correlation between number of children (X) and hours per week husband spends on housework (Y) is not statistically significant

Correlation matrix

- Table that shows the associations between all possible pairs of variables
 - Which are the strongest and weakest associations among birth rate, education, poverty, and teen births?

A Correlation Matrix Showing the Relationships Among Four Variables

	1	2	3	4
	Birth Rate	Education	Poverty	Teen Births
1. Birth Rate	1.00	-0.24	0.16	0.26
2. Education	-0.24	1.00	-0.71	-0.78
3. Poverty	0.16	-0.71	1.00	0.88
4. Teen Births	0.26	-0.78	0.88	1.00

KEY: "Birth Rate" is number of births per 1000 population.

"Education" is percentage of the population with a college degree or more.

"Poverty" is percentage of families below the poverty line.

"Teen Births" is the percentage of all births to teenagers.
